Fanconi syndrome is characterized by global dysfunction of the proximal renal tubule resulting in the loss of amino acids, glucose, bicarbonate, sodium, potassium and phosphate through the kidneys. The primary abnormalities seen with this syndrome are hyperchloremic acidosis, polyuria, intravascular volume depletion, growth retardation, rickets, and hypokalemia.

Fanconi's syndrome has multiple causes including cystinosis, Wilson's disease, galactosemia, and glycogenosis. Exposure to heavy metals, tetracycline, and chemotherapy agents can also produce the syndrome.

Patients with Fanconi's syndrome who are presenting for surgery will likely require sodium, potassium and fluid replacement, correction of acidosis, and supplementation of vitamin D and phosphate.

Fanconi's syndrome involves global dysfunction of the proximal tubule.
